Research in motion

Five Levels of Vehicle Autonomy

Level 0

No automation:
the driver is in complete control of the vehicle at all times.

Level 1

Driver assistance:
the vehicle can assist the driver or take control of either the vehicle's speed, through cruise control, or its lane position, through lane guidance.

Level 2

Occasional self-driving:
the vehicle can take control of both the vehicle's speed and lane position in some situations, for example on limited-access freeways.

Level 3

Limited self-driving:
the vehicle is in full control in some situations, monitors the road and traffic, and will inform the driver when he or she must take control.

Level 4

Full self-driving under certain conditions:
the vehicle is in full control for the entire trip in these conditions, such as urban ride-sharing.

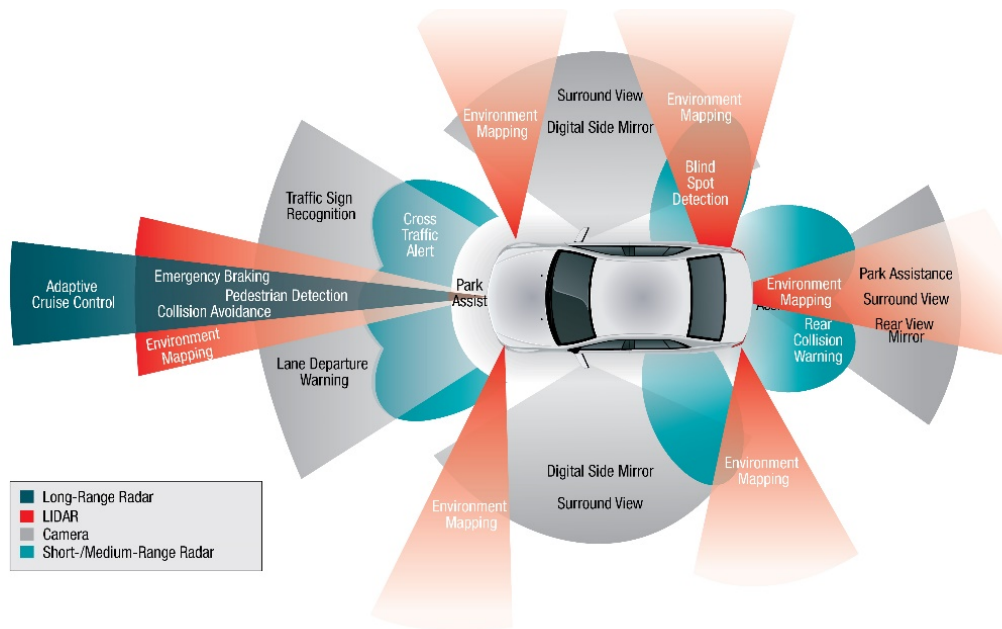

Level 5

Full self-driving under all conditions:
the vehicle can operate without a human driver or occupants.

How does an automated vehicle perceive the world?

Automation and ITS saves plenty of lives..

- AEB has been shown to reduce such collisions by 38%, according to research by the safety organisation Euro NCAP.
- ACC - At high speeds (~110kph) jamming occurs for concentrations of ACC vehicles of 10% or less. At 20% no jams are formed².
- By 2020, 2.7% of single-vehicle lane departure crashes could be avoided if 8.5% of the fleet has Lane Departure Warning with 20% effectiveness¹.
 - *If the LDP system is 100% effective by 2045, 66.5% of the single-vehicle lane departure crashes can be prevented.*
 - *LDW - Vehicles with LDW had significantly lower involvement rates in crashes of all severities (18%), in those with injuries (24%), and in those with fatalities (86%)³*
- blind-spot detection systems—usually warning lights in side mirrors—found the systems lower the rate of all lane-change crashes by 14 percent and the rate of such crashes with injuries by 23 percent⁴.

Adaptive cruise control

- Adaptive cruise control comes with many advantages
 - *Offloading the driver*
 - *More efficient traffic flow*
 - *Safer following distances*

- But...
- Most contemporary ACC systems ignore stationary objects
 - *E.g. Tesla crashes with stationary EMS vehicles on the hard-shoulder*
 1. *Handan, China (January 20, 2016) – stationary vehicle*
 2. *Williston, Florida (May 7, 2016) – tractor trailer*
 3. *Culver City, California (January 22, 2018) – fire truck*
 4. *Mountain View, California (March 23, 2018) – concrete barrier*
 5. *South Jordan, Utah (May 11, 2018) – fire truck*

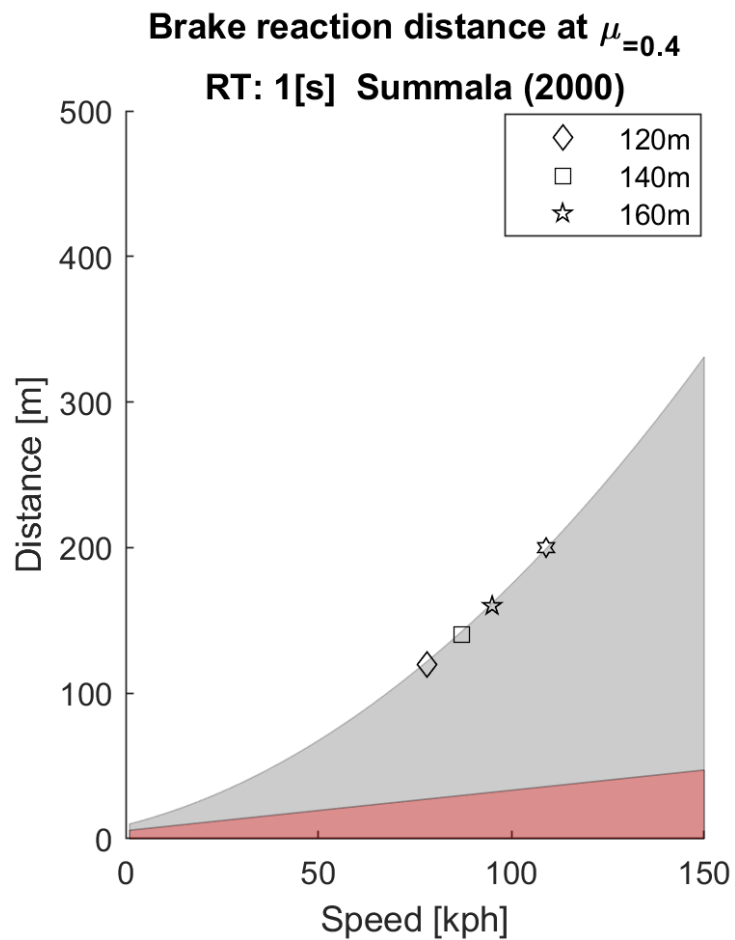

Five Levels of Vehicle Autonomy

Automation leads to longer driver reaction-times

Level 3 Automation

- *In the event of a DDT performance-relevant system failure in a level 3 ADS or in the event that the ADS will soon exit its ODD, the ADS will issue a request to intervene **within sufficient time** for a **typical person** to respond **appropriately** to the driving situation at hand” (SAE J3016, 2016)*
- Could be caused by:
 - *Sensor issues*
 - *Flat tire*
 - *Broken tire-rod*
 - *In essence, any vehicle related issue...*

Level 3 Automation

- Humans are not very good at monitoring a situation with little changes for long durations.
- This leads to...
 - *Attention decrements*
 - *Loss of vigilance*
 - *Distraction*
 - *Long reaction times*
 - *Poor vehicle control*

The Uber crash in Tempe, Arizona

So for how long are we expected to interact with such problematic systems?

Grad av automatisering i kjøretøy, basert på nivåene til Society of Automotive Engineers (SAE):

● Nivå 2 ● Nivå 3 ● Nivå 4
